The Locals began in the 1850s partly because they were seen to be a fair way to identify and reward ability. Twenty years later the boards were working out their responses to accusations of not being fair. It is how far the present examination system is seen as being fair to individuals which will make the difference between it being perceived as a liberalising or a reactionary one. Independent examining boards are well-placed to respond to this challenge and they continue to play an important part in maintaining the credibility of that system.

PSYCHOLOGY OF ASSESSMENT

Investigating the judgemental marking process: an overview of our recent research

Dr Irenka Suto, Victoria Crisp and Dr Jackie Greatorex Research Division

Prior to Cambridge Assessment’s recent interest in the area, the process of marking GCSE and A-level examination questions had received surprisingly little attention among psychologists and social scientists. Whilst there has been some research into marking processes in other contexts (e.g. English essay marking: Barritt, Stock and Clark, 1986, Pula and Huot, 1993; English as a second language: Cumming, 1990, Vaughan, 1991, Milanovic, Saville and Shuhong, 1996, Lumley, 2002) to our knowledge, only Sanderson (2001) has explored the process in depth, producing a socio-cognitive model of A-level essay marking. To address this dearth in knowledge, members of the Core Research team have conducted several linked projects, considering the marking process from different angles. Key aims have been to provide insights into how examiner training and marking accuracy could be improved, as well as reasoned justifications for how item types might be assigned to different examiner groups in the future.

As with any major research question, the issue of how examiners mark items needs to be explored from many different angles to gain as full and cohesive an answer as possible. In biological research, for example, the nature and effects of an illness are explored at multiple levels: molecular, intra-cellular, cellular, physiological, whole organisinal, and even epidemiological and demographic. Similarly, some physics researchers conduct fine-grained analyses of minute particles, while others monitor massive structures in space, both in their attempts to establish how the universe began. Linking together these jigsaw pieces in order to see the bigger picture and gain a real overview of a process or phenomenon can be a difficult but necessary challenge. As with biology and physics, this is an important task for researchers in educational assessment.

To recognise the different approaches to research and analysis that the marking process engenders, it is worth considering the very broad research field in which it primarily lies – that of human judgement and decision-making. There exist a number of well-established approaches to investigation, adopted by researchers working within diverse paradigms, and as with the natural sciences, questions are explored on a number of levels. For example, a key approach has been to ask what information people attend to and utilise when making decisions. On perhaps the most ‘fine-grained’ level of research, cognitive psychologists have identified and scrutinised shifts in visual attention among small pieces of information, such as letters, numbers and words on a page of writing. At another level, other psychological researchers have focused on cognitive heuristics and biases in information processing. At yet another level, the influences and roles of behavioural and social information have been explored by researchers interested in such dynamics, and at yet another level still, the effects of physical information in the environment have been studied. Studies at all of these levels have provided important contributions to our understanding in the research field, although there is the potential for them to be integrated much more.

Another popular approach to understanding judgement and decision-making has been to explore the sequences of mental operations by which people arrive at their choices. This approach has proven particularly popular in clinical and legal settings, and again, it has been adopted at a number of levels. In the Core Research team’s work on the marking process, we have combined this approach with the one outlined above:
A second closely-linked project (Greatorex and Suto, 2006) entailed re-analysing the verbal protocols of ‘expert’ and ‘subject’ markers who had marked GCSE maths and A-level physics papers on screen. The data provided further evidence for the five cognitive strategies, indicating that they are used in other marking contexts. As part of a subsequent project, entitled Marking Expertise 1, we explored the relationship between cognitive marking strategy complexity and marking accuracy (Suto and Nádas, 2007a; Suto and Nádas, in press). A new theoretical framework was constructed, conceptualising marking accuracy for a particular question as being determined by both (i) a marker’s expertise, and (ii) the demands of the marking task. It was proposed that these two factors are in turn affected by a number of different variables, including the complexity of the marking strategies needed to mark the question, and utilisation knowledge of the marking strategies (i.e. knowing which strategies to apply when).

The question-by-question marking of GCSE maths and physics by our projects explore both the information that people attend to when marking items and the sequences of mental operations involved.

At a relatively fine-grained level, in our first project, entitled Markers’ Minds, we identified the cognitive marking strategies entailed in marking GCSE maths and business studies questions (Suto and Greatorex, in press, a). This was done using the think aloud method with experienced examiners (Greatorex and Suto, in submission). Working within the ‘dual-processing’ paradigm (Kahneman and Frederick, 2002), we interpreted two of our five strategies (matching and no response) as utilising simple ’System 1’ or ‘intuitive’ judgemental processes, two strategies (scrutinising and evaluating) as utilising more complex ‘System 2’ or ‘reflective’ processes, and one strategy (scanning) as engaging System 1 and/or System 2. An analysis of strategy usage (Greatorex and Suto, 2005; Suto and Greatorex, in press, b) revealed that although there are some differences among individual examiners, the most prominent differences occur between subjects and among questions.

Figure 1: A summary of the influences and processes that have been identified in our research as important to the marking process
2. Crisp (2007a; 2007b; 2007c)
3. Crisp (in press)
5. Crisp (2007a; 2007b; in press; in submission)
11. Crisp (2007b; 2007c; in press; in submission)
‘expert’ and ‘graduate’ markers was explored, and it was found that the apparent marking strategy complexity that a question entails is indeed associated with the accuracy with which it is marked. (Instead of using the think aloud method to demonstrate which marking strategies were used, researchers rated the marking strategy complexity of each question a priori.) The finding was replicated in a study of A-level biology marking (Internalising Mark Schemes, reported as part of Greatorex, Nádas, Suto and Bell, 2007). Furthermore, one finding was that apparent marking strategy complexity was a useful indicator of how much the standardisation meeting improves marking accuracy; this was the case for two of the three subjects investigated (Greatorex et al., 2007). In Marking Expertise 1, apparent marking strategy usage was also found to be associated with various subject-specific question features, which are in turn associated with accuracy (Suto and Nádas, 2007b).

These projects have been generally well received, and researchers outside Cambridge Assessment who attended conference presentations of the Markers’ Minds research have been interested to know how the cognitive strategies relate to other more socio-cognitive perspectives. This question has begun to be addressed in another project: Holistic versus Structured marking (Crisp, 2007a; 2007b; in press; in submission). The primary aim of this research was to compare the process of marking short/medium answer questions with that of marking essays. This was achieved in the context of A-level geography, again using the think aloud method to collect data from examiners. This time, however, the analysis was broader, covering a number of different levels. Several well-established theoretical perspectives were brought into the analysis: constructivist theories of reading comprehension, discourse communities, and communities of practice.

A number of types of examiner behaviours and reactions were identified which were compared between question types within the qualification (Crisp, 2007a; Crisp, in press). The framework was also used to explore individual differences among examiners, a considerable number of which were revealed. Possible associations between marker behaviours and lower marker agreement were investigated leading to tentative implications (Crisp, 2007a; Crisp, in press). The appropriateness of the features that examiners attended to was also analysed (Crisp, 2007b). A broad socio-cognitive model bringing together the behaviours and reactions observed was proposed to represent the phases (and loops) involved in the process of marking responses. Links between the proposed model and existing psychological theories of judgement were also explored (Crisp, in submission).

The programme of research has now investigated marking in GCSE and A-levels in a number of subjects, for a range of question types and from a number of different perspectives. The diagram in Figure 1 summarises the influences and processes that have been identified as important to the marking process from the research conducted so far. The footnotes indicate which papers report on findings in each area.

Whilst the Core Research team have now contributed significantly to an understanding of GCSE and A-level marking, our investigations are ongoing. As part of some doctoral research, the process of marking coursework is being investigated from a socio-cognitive angle. In Marking Expertise 2 (Suto and Nádas, 2007a), we are continuing to explore the associations between marking accuracy, apparent marking strategy complexity and question features, this time within the context of GCSE business studies and IGCSE biology marking. In other work the judgement processes involved in moderating vocational portfolios (Johnson and Greatorex, 2007) and grading decisions are being explored.

An exploration of self-confidence and insight into marking accuracy among GCSE maths and physics markers

Rita Nádas and Dr Irenka Suto  Research Division

Background

Introduction

A considerable volume of literature in education and occupational research investigates issues in self-confidence and insight, ranging from college students’ post-diction self-assessment (e.g. Maki, 1998; Koch, 2001) to work-related self-assessment (Dunning, Heath and Suls, 2004). However, GCSE markers’ perceptions of their marking performance and their metacognition have not, to our knowledge, been examined.

Exploring markers’ perceptions is important for several reasons. First, if markers’ estimates of their own performance prove to be accurate, then this information could be used by Awarding Bodies in standardisation procedures1 to identify and discuss examination questions that markers felt difficult to mark accurately than others. In: M. M. Williamson & B. Huot (Eds.), Validating holistic scoring for writing assessment: theoretical and empirical foundations. Cresskill, NJ: Hampton.

PSYCHOLOGY OF ASSESSMENT

An exploration of self-confidence and insight into marking accuracy among GCSE maths and physics markers

Rita Nádas and Dr Irenka Suto  Research Division

Background

Introduction

A considerable volume of literature in education and occupational research investigates issues in self-confidence and insight, ranging from college students’ post-diction self-assessment (e.g. Maki, 1998; Koch, 2001) to work-related self-assessment (Dunning, Heath and Suls, 2004). However, GCSE markers’ perceptions of their marking performance and their metacognition have not, to our knowledge, been examined.

Exploring markers’ perceptions is important for several reasons. First, if markers’ estimates of their own performance prove to be accurate, then this information could be used by Awarding Bodies in standardisation procedures1 to identify and discuss examination questions that markers have difficulties with. If, however, markers’ insight proves to be unreliable and unrelated to their actual marking accuracy, then their feedback on ‘problem areas’ could be misleading; for example, when conducting standardisation procedures, Principal Examiners might find themselves focussing on the ‘wrong’ questions. Secondly, investigating whether self-confidence and insight change or become more accurate with more marking practice or more feedback could inform the marker training practices of Awarding Bodies. This may thereby enhance marking accuracy: there is evidence that improvement of one’s self-assessment or insight into performance results in enhanced test performance (Koch, 2001; Dunning, Johnson, Ehrlinger and Kruger, 2003).

In this article we present the aims and findings of research which explored GCSE markers’ perception of their own marking performance, namely, marking accuracy. Markers’ levels of self-confidence and insight and possible changes in these measures over the course of the marking process were investigated. The term ‘self-confidence’ here denotes markers’ post-marking estimates of how accurately they thought they had marked a sample of questions; ‘insight’ refers to the relationship between markers’ actual marking accuracy and estimated accuracy, indicating how precise their estimates were.

Theories of insight and self-confidence

Insight into performance has been widely researched from various angles; and it has generally been found that people tend to have incorrect estimations of their own performance. For example, Dunning et al. (2003) found that when asked to predict their mastery on an examination, students in the bottom quartile greatly overestimated their actual performance. They also found that the better performing students were able to predict their raw scores with more accuracy, with top performers actually slightly underestimating their scores.

Several theories have been proposed to explain the phenomenon of poor insight. The nature of self-confidence has been examined by cognitive psychologists, who have adopted the ‘self-serving bias’ theory. Researchers have found that biases are used by participants in research...
